## Economics 620, Lecture 7:

## Still More, But Last, On the $K$-Variable Linear Model

Specification Error:

Suppose the model generating the data is

$$
y=X \beta+\varepsilon
$$

However, the model fitted is $y=X^{*} \beta^{*}+\varepsilon$, with the LS estimator

$$
\begin{aligned}
& b^{*}=\left(X^{* \prime} X^{*}\right)^{-1} X^{* \prime} y \\
& =\left(X^{* \prime} X^{*}\right)^{-1} X^{* \prime} X \beta+\left(X^{* \prime} X^{*}\right)^{-1} X^{* \prime} \varepsilon .
\end{aligned}
$$

Then $E b^{*}=\left(X^{* \prime} X^{*}\right)^{-1} X^{* \prime} X \beta$ and $V\left(b^{*}\right)=\sigma^{2}\left(X^{* \prime} X^{*}\right)^{-1}$

## Application 1: Excluded variables

Let $X=\left[X_{1} X_{2}\right]$ and $X^{*}=X_{1}$.
That is, the model that generates the data is

$$
y=X_{1} \beta_{1}+X_{2} \beta_{2}+\varepsilon .
$$

Consider $b^{*}$ as an estimator of $\beta_{1}$.

Proposition: $b^{*}$ is biased.
Proof:

$$
\begin{aligned}
b^{*} & =\left(X^{* \prime} X^{*}\right)^{-1} X^{* \prime} y \\
& =\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime}\left(X_{1} \beta_{1}+X_{2} \beta_{2}+\varepsilon\right) \\
& =\beta_{1}+\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime} X_{2} \beta_{2}+\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime} \varepsilon \\
E b^{*} & =\beta_{1}+\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime} X_{2} \beta_{2}
\end{aligned}
$$

The second expression on the right hand side is the bias.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## A classic example:

Suppose that the model generating the data is
$y_{i}=\beta_{0}+\beta_{1} S_{i}+a_{i}+\varepsilon_{i}$
$y$ : natural logarithm of earnings
$S$ : schooling
$a$ : ability
$a$ is unobserved and omitted, but it is positively correlated with $S$.

Then

$$
E b^{*}=\left[\begin{array}{c}
\beta_{0} \\
\beta_{1}
\end{array}\right]+\left[\begin{array}{cc}
N & \sum S \\
\sum S & \sum S^{2}
\end{array}\right]^{-1}\left[\begin{array}{c}
\sum a \\
\sum a S
\end{array}\right]
$$

supposing $a$ is measured so that its coefficient is 1 .

If we suppose that $\sum a=0$, then the bias in the coefficient of schooling is positive.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## A classic example (cont'd)

Generally, we cannot sign the bias, it depends not only on $\beta_{2}$ but also on $\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime} X_{2}$, which of course can be positive or negative.

Note that $V b^{*}=\sigma^{2}\left(X_{1}^{\prime} X_{1}\right)^{-1}$. So if $\beta_{2}=0$, there is an efficiency gain from imposing the restriction and leaving out $X_{2}$. This confirms our earlier results.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

Estimation of $\sigma^{2}$ :

$$
\begin{aligned}
& e^{*}=M_{1} y=M_{1}\left(X_{1} \beta_{1}+X_{2} \beta_{2}+\varepsilon\right) \\
& =M_{1} X_{2} \beta_{2}+M_{1} \epsilon \\
& \Rightarrow e^{* \prime} e^{*}=\beta_{2}^{\prime} X_{2}^{\prime} M_{1} X_{2} \beta_{2}+\varepsilon^{\prime} M_{1} \varepsilon+2 \beta_{2}^{\prime} X_{2}^{\prime} M_{1} \epsilon
\end{aligned}
$$

Note the expected value of the last term is 0 .

Clearly, we cannot estimate $\sigma^{2}$ by usual methods even if $X_{1}^{\prime} X_{2}=0$ (no bias) since still $M_{1} X_{2} \neq 0$.

There is hope of detecting misspecification from the residuals since $E e^{*} e^{* \prime}=\sigma^{2} M_{1}$ under correct specification and $E e^{*} e^{* \prime}=\sigma^{2} M_{1}+M_{1} X_{2} \beta_{2} \beta_{2}^{\prime} X_{2}^{\prime} M_{1}$ under misspecification.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Application 2:

Inclusion of unnecessary variables.

Let $X=X_{1}$ and $X^{*}=\left[\begin{array}{ll}X_{1} & X_{2}\end{array}\right]$
$X_{1}$ is $N \times K_{1}$ and $X_{2}$ is $N \times K_{2}$.

That is, the "true" model is $y=X_{1} \beta+\varepsilon$.

Proposition: $b^{*}$ is unbiased.

Proof: $E b^{*}=\left(X^{* \prime} X^{*}\right)^{-1} X^{* \prime} X \beta$

$$
=\left[\begin{array}{ll}
X_{1}^{\prime} X_{1} & X_{1}^{\prime} X_{2} \\
X_{2}^{\prime} X_{1} & X_{2}^{\prime} X_{2}
\end{array}\right]^{-1}\left[\begin{array}{l}
X_{1}^{\prime} X_{1} \\
X_{2}^{\prime} X_{1}
\end{array}\right] \beta
$$

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

The partitioned inversion formula gives

$$
\left[\begin{array}{cc}
\Gamma & -\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime} X_{2} D \\
-D X_{2}^{\prime} X_{1}\left(X_{1}^{\prime} X_{1}\right)^{-1} & D
\end{array}\right]
$$

for $\left(X^{* \prime} X^{*}\right)^{-1}$ where $D=\left(X_{2}^{\prime} M_{1} X_{2}\right)^{-1}$ and
$\Gamma=\left(X_{1}^{\prime} X_{1}\right)^{-1}+\left(X_{1}^{\prime} X_{1}\right)^{-1} X_{1}^{\prime} X_{2} D X_{2}^{\prime} X_{1}\left(X_{1}^{\prime} X_{1}\right)^{-1}$.

This is a symmetric matrix. Multiplying this out verifies that

$$
E b^{*}=\left[\begin{array}{l}
\beta \\
0
\end{array}\right]
$$

Note that the variance of $b^{*}$ is

$$
V\left(b^{*}\right)=\sigma^{2}\left(X^{* \prime} X^{*}\right)^{-1}
$$

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

Proposition: The variance of the coefficients of $X_{1}$ in the unrestricted (where the matrix of explanatory variables is $X^{*}$ ) is greater than the variance of the coefficients in the restricted model (where the matrix of explanatory variables is $X_{1}$ ).

Proof: Using partitioned inversion, the variance of the first $K_{1}$ elements (coefficients on $X_{1}$ ) is $\sigma^{2}\left(X_{1}^{\prime} M_{2} X_{1}\right)^{-1} \geq$ $\sigma^{2}\left(X_{1}^{\prime} X_{1}\right)^{-1}=$ variance of the restricted estimator. (why?)

Estimation of $\sigma^{2}$ :
$e^{*}=M^{*} y=M^{*} \varepsilon$

Under normality,
$\left(e^{* \prime} e^{*} / \sigma^{2}\right)=\left(\varepsilon^{\prime} M^{*} \varepsilon / \sigma^{2}\right) \sim \chi^{2}\left(N-K_{1}-K_{2}\right)$
$\Rightarrow s^{2}$ has higher variance than in the restricted model. (why?)
Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Note on the interpretation of bias:

$E y=X \beta$ defines $\beta$ and $L S$ gives unbiased estimates of that $\beta$. Questions of bias really require a model.

Further statistical assumptions like

$$
V y=\sigma^{2} I
$$

allow some sorting out of specifications, but is this assumption really attractive?

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Cross products matrix:

In $L S$, "everything" comes from the cross products matrix.

Definition: The cross products matrix is

$$
\left[\begin{array}{cc}
y^{\prime} y & y^{\prime} X \\
X^{\prime} y & X^{\prime} X
\end{array}\right]=\left[\begin{array}{cccc}
\sum y_{i}^{2} \sum y_{i} \sum y_{i} x_{2 i} & \cdots \sum y_{i} x_{K i} \\
\bullet & \sum 1 & \sum x_{2 i} \cdots \sum x_{K i} \\
\bullet & \bullet & & \sum x_{2 i}^{2} \cdots \sum x_{2 i} x_{K i} \\
\bullet & \bullet & \bullet & \cdots \sum x_{K i}^{2}
\end{array}\right]
$$

with a column of ones in $X$.

It is a symmetric matrix.

Note that $x_{j}$ refers to the $j$ th column of $X$.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Heteroskedasticity

$V(Y)=V \neq \sigma^{2} I$
Is the $L S$ estimator unbiased? Is it BLUE?

Proposition: Under the assumption of heteroskedasticity, $V(\widehat{\beta})=\left(X^{\prime} X\right)^{-1} X^{\prime} V X\left(X^{\prime} X\right)^{-1}$.

Proof:
$V(\hat{\beta})=E\left(X^{\prime} X\right)^{-1} X^{\prime} \varepsilon \varepsilon^{\prime} X\left(X^{\prime} X\right)^{-1}$
$=\left(X^{\prime} X\right)^{-1} X^{\prime} V X\left(X^{\prime} X\right)^{-1}$.
Suppose $\sum=V(\varepsilon)$ is a diagonal matrix. Then

$$
X^{\prime} \sum X=E \sum X_{i} \varepsilon_{i}^{2} X_{i}^{\prime}
$$

Note that the cross products have expectation 0 .
This suggests using $\sum X_{i} e_{i}^{2} X_{i}^{\prime}$.
So we can estimate standard errors under the assumption that $V(y)$ is diagonal.
Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Testing for heteroskedasticity:

## 1. Goldfeld-Quandt test:

Suppose we suspect that $\sigma_{i}^{2}$ varies with $x_{i}$. Then reorder the observations in the order of $x_{i}$. Suppose $N$ is even. If $\varepsilon$ was observed, then

$$
\frac{\varepsilon_{1}^{2}+\varepsilon_{2}^{2}+\ldots+\varepsilon_{N / 2}^{2}}{\varepsilon_{[(n / 2)+1]}^{2}+\varepsilon_{[(N / 2)+2]}^{2}+\ldots+\varepsilon_{N}^{2}} \sim F(N / 2, N / 2)
$$

could be used.

We are tempted to use $e_{i}$, but we can't because the first $N / 2 e_{i}$ 's are not independent of the last.

Here comes the Goldfeld-Quandt trick: Estimate $e$ separately for each half of the sample with $K$ parameters. The statistic is $F((N / 2)-K,(N / 2)-K)$.

It turns out that this "works" better if you delete the middle $N / 3$ observations.
Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Testing for heteroskedasticity (cont'd):

2. Breusch-Pagan test:

The disturbances $\varepsilon_{i}$ are assumed to be normally and independently distributed with variance $\sigma_{i}^{2}=h\left(z_{i}^{\prime} \alpha\right)$ where $h$ denotes a function, and $z_{i}^{\prime}$ is a $1 \times P$ vector of variables influencing heteroskedasticity.

Let $Z$ be an $N \times P$ matrix with row vectors $z_{i}^{\prime}$. Some of the variables in $Z$ could be the same as the variables in $X$.

Regress $e^{2} / \sigma_{M L}^{2}$ on $Z$, including an intercept term.

Note that (sum of squares due to $Z$ ) $/ 2 \sim \chi^{2}(P-1)$ approximately. The factor $1 / 2$ appears here since under normality the variance of $\varepsilon^{2} / \sigma^{2}$ is $2\left(E \varepsilon^{4}=3 \sigma^{4}\right)$.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Testing for heteroskedasticity (cont'd):

An alternative approach (Koenker) drops normality and estimates the variance of $e_{i}^{2}$ directly by $N^{-1} \sum\left(e_{i}^{2}-\right.$ $\left.\hat{\sigma}^{2}\right)^{2}$. The resulting statistic can be obtained by regressing $e^{2}$ on $z$ and looking at $N R^{2}$ from this regression.

Other tests are available for time series.

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Testing Normality

The moment generating function of a random variable $x$ is $m(t)=E(\exp (t x))$; note $m^{\prime}(0)=E x ; m^{\prime \prime}(0)=$ $E x^{2}$; etc.

The MGF of the normal distribution $n\left(\mu, \sigma^{2}\right)$ is $m(t)=$ $\exp \left(t \mu+t^{2} \sigma^{2} / 2\right)$.

Proof:
let $c=(2 \pi \sigma)^{-1 / 2}$

$$
\begin{aligned}
m(t) & =c \int \exp (t x) \exp \left(-1 / 2(x-\mu)^{2} / \sigma^{2}\right) d x \\
& =c \int \exp \left(-1 / 2\left(x-\mu-\sigma^{2} t\right)^{2} / \sigma^{2}+t \mu+\sigma^{2} t^{2} / 2\right) d x \\
& =\exp \left(t \mu+\sigma^{2} t^{2} / 2\right)
\end{aligned}
$$

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.

## Testing Normality (cont'd)

Thus for the regression errors $\varepsilon$ we have $E \varepsilon=0 ; E \varepsilon^{2}=\sigma^{2} ; E \varepsilon^{3}=0 ; E \varepsilon^{4}=3 \sigma^{4} ; E \varepsilon^{5}=0$; etc.

It is easier to test the 3rd and 4th moment conditions than normality directly.

If we knew the $\varepsilon$, it would be easy to come up with a $\chi^{2}$ test.

In fact a test can be formed using the residuals $e$ instead (and relying on asymptotic distibution theory). The test statistic is

$$
\left.n\left[\overline{\left((e / s)^{3}\right)^{2}} / 6+\overline{\left((e / s)^{4}\right.}-3\right)^{2} / 24\right]
$$

Which is $\chi^{2}$ with $2 d f$.

This is the Kiefer/Salmon test (also called Jarque/Bera).

Prof. N. M. Kiefer, Econ 620, Cornell University, Lecture 7. Copyright (c) N. M. Kiefer.
